

Volatility Report

Generated 23/09/2026, 19:25:01

Statistics on where the last 500 crashed rounds actually crashed. Use this to sanity-check that the live game behaves as the configured house edge predicts and to spot anomalies.

Crash Point Statistics

The "crash point" is the multiplier at which a round ended. The mean is pulled up by rare very high crashes, so the median (the middle value) better reflects a typical round. Standard deviation measures how spread out crash points are. P10 means 10% of rounds crashed at or below that value; P90 means 90% did.

Rounds sampled	500
Mean crash point	3.2x
Median crash point	1.9x
Standard deviation	8.1
P10 / P90	1.05x / 7.2x
P25 / P75	1.3x / 3.4x

Crash Point Distribution

How many sampled rounds crashed within each multiplier range. In a fair crash game most rounds end at low multipliers, with the share falling steadily as the range increases.

Range	Rounds	Share of Sample
1.00-1.50x	200	40%
1.50-2.00x	100	20%
2x+	200	40%
